Unit 3 : Session 11 : SLO 2 | Create Form-Based Input and Process Flow Using Swing

I. Fill in the Blanks

1. `getText()` retrieves the text entered into a `JTextField`.
2. `Integer.parseInt()` converts the field text to an `int`.
3. `add()` adds the button to the form panel.
4. `JOptionPane` is used to display simple pop-up message dialogs in Swing.

II. True or False

1. FALSE — `JTextArea` is for multi-line input; `JTextField` is the single-line component.
2. TRUE — `getText()` returns a `String`, so it must be parsed (e.g. `Integer.parseInt()`) before numeric operations.

III. Multiple Choice

1. C — `button.addActionListener()` registers a click handler.
2. C — `GridLayout` gives the structured rows-and-columns arrangement suited to forms.

IV. Programming

1. Output: B — clicking Submit prints the field's current text, "John".
2. Missing logic: B — `JOptionPane.showMessageDialog(null, "Hello " + name)` shows the greeting in a pop-up dialog.
