Unit 4 : Session 7 : SLO 1 | Multiprocessing Using IPython

■ I. Fill in the Blanks

1. The multiprocessing module “ it spawns separate OS processes so Python code runs truly in parallel (bypassing the GIL).
2. Pool “ a Pool manages a group of worker processes and distributes tasks among them.

■ II. Multiple Choice

1. [1, 4, 9] “ p.map(square, [1, 2, 3]) applies square() to each element across 2 worker processes and returns the results in order.

■ III. Key Notes

- Pool(n) creates n worker processes; the with block ensures workers are closed and joined.
- map() preserves input order regardless of which process finished first.
